

Building an AI-Powered Career Product

ZYORO AI — From user problem to AI-enabled product workflows

Case study focus
How I use generative AI to turn a real user problem into practical product features, while balancing usefulness, relevance, user experience, and engineering feasibility.

1. The User Problem

Job seekers often use separate tools for resume feedback, ATS optimization, interview preparation, job discovery, and application decisions. The information is fragmented, and generic advice is often not actionable for a specific candidate or target role.

2. Product Idea

I built Zyoro AI as an AI-powered career platform designed to bring these workflows together. The product uses a candidate's resume, target role, company context, and job information to produce personalized insights instead of one-size-fits-all recommendations.

3. Turning AI Into Product Features

Resume Intelligence Analyze resumes, identify strengths and missing areas, and provide actionable improvement suggestions.	ATS & Role Optimization Evaluate alignment with target roles and help users understand keyword, skill, and experience gaps.
AI Interview Preparation Generate role/company-focused interview questions and answers based on the candidate's profile.	AI Interview Evaluation Use AI-driven feedback to assess interview responses and highlight areas for improvement.
Job Matching Compare candidate skills with job requirements and provide a useful match perspective.	Career Workflow Connect analysis, preparation, and job discovery into a more continuous user journey.

4. My Approach to Using AI

- Start with the user outcome: define what the user should be able to do better after the AI interaction.
- Provide the right context: pass relevant resume, role, company, or job information instead of relying on generic prompts.
- Make outputs actionable: convert model output into scores, gaps, recommendations, questions, or next steps.
- Validate and iterate: review AI responses for relevance, edge cases, consistency, and usability, then improve the workflow.

AI Product Case Study — Zyoro AI

Product thinking, AI integration, and engineering execution

5. Example Workflow: Resume → Personalized Interview Preparation

1. Input Resume + target role/company	2. Understand Extract relevant skills, experience and context	3. Generate Create role-relevant interview material	4. Improve Use feedback to identify preparation gaps
---	---	---	--

6. Technical Execution

The product is supported by a full-stack engineering approach. My work includes designing backend APIs and integrating AI capabilities into application workflows rather than treating the model as a standalone chatbot.

Layer	Relevant technologies / responsibilities
Backend	Node.js, Express.js, REST APIs, MongoDB/Mongoose
AI	Gemini API integration, prompt/context design, AI-generated analysis and feedback
Document processing	Resume/PDF upload and parsing, structured extraction and generated documents
Security	JWT authentication, protected APIs, environment-based secrets
Frontend	React-based product interfaces and user workflows

7. What I Learned About AI Product Development

- AI is valuable when it solves a specific user problem. A technically impressive model response is not automatically a useful product feature.
- Context drives quality. Supplying relevant user and role information makes AI output more personalized and useful.
- Product UX matters as much as the model. Scores, explanations, recommendations and clear next actions make AI easier to trust and use.
- Iteration is essential. AI outputs need continuous review for relevance, edge cases and consistency.

8. Why This Matters for a Product Team

My strength is the combination of engineering execution and product-oriented problem solving. I can understand a user problem, translate it into a workflow, integrate AI where it creates value, build the supporting APIs, and iterate on the experience based on the quality of the outcome.
